

# Alberta Commercial Lodging Performance and Building Energy Model Input Calibration Report

## Standardized Monthly Lodging Performance Series

The following data table presents the historical monthly performance metrics for the commercial lodging channel in the province of Alberta<sup>1</sup>. The operational parameters are structured to support the guest-room schedule within the GSS→BEM pipeline<sup>1</sup>. In compliance with data-integrity protocols designed to prevent downstream model bias, only raw, verified values are reported, and any unobtained records are strictly designated as gaps<sup>1</sup>. Due to the unavailability of the historical monthly micro-data within the session's verified public payloads, the 216-month window spanning 2005-01 to 2022-12 is designated as an unobtained series gap<sup>1</sup>. This prevents the propagation of fabricated baselines into the pipeline's modeling gates<sup>1</sup>.

## Source Citation and Data Accessibility Audit

This narrative section and accompanying markdown table detail the provenance, access pathways, sample parameters, and verified status of the data channels used to construct the lodging performance series<sup>1</sup>. Due to strict data governance protocols, any administrative API or government endpoints that cannot be successfully accessed or verified are excluded<sup>1</sup>. This includes the non-functional `api.economicdata.alberta.ca` endpoint, which was identified as invalid in previous data-collection attempts<sup>1</sup>. Instead, raw verified data is traced directly to landing pages on the official Alberta Economic Dashboard and corporate CBRE portals<sup>1</sup>.

|--|--|---------------------------------------------------------|--------------------|-----------------|--------------------------------------------------------------------------|-----------------------------------------------------------|

The web retrieval session confirmed the presence of active indicator pages on the Alberta Economic Dashboard<sup>2</sup>. For instance, on the Accommodation Occupancy Rate landing page, the live text states that in April 2026, Alberta hotels excluding resorts had an occupancy rate of 58.1%, which was 0.6 percentage points higher than in April 2025<sup>2</sup>. Similarly, on the Average Daily Room Rate page, the nominal average non-resort room rate is recorded at \$155.67 for April 2026, registering a 4.3% expansion over April 2025<sup>5</sup>. On the Revenue Per Available Room page, the non-resort RevPAR is listed as \$90.46 for April 2026<sup>4</sup>.

These verified snapshots confirm the operational status of the portals<sup>2</sup>. However, because the historical monthly dataset (spanning 2010 to 2022) is not explicitly compiled in the session's research data, those months are designated as gaps in the standardized monthly table to prevent the introduction of fabricated or synthetic values<sup>1</sup>.

## Sanity Metrics and Quality Reconciliation

To evaluate the mathematical and seasonal alignment of the lodging series prior to downstream SARIMA model training or energy schedule design, the extracted parameters must be verified against standard physical limits and historical benchmarks<sup>1</sup>. This process flags any anomalous values or structural breaks that could lead to inaccurate energy consumption modeling<sup>1</sup>.

| Check                                                                     | Expected (dr_L3-01)             | Your extracted value | Pass / Flag                                                                                 |

|                                                                |                                                                                    |     | current payload <sup>2</sup>                                                                        |
| <b>Seasonal shape sanity</b>                                   | Summer peak (July/August) > Winter trough (December/January) <sup>6</sup>          | GAP | <b>Flagged:</b> Inability to construct seasonal profile due to missing monthly records <sup>2</sup> |
| <b>ABDASH-vs-CBRE level at 2010 overlap (if CBRE obtained)</b> | CBRE raw provincial average ~2–4 percentage points higher than ABDASH <sup>1</sup> | GAP | <b>Flagged:</b> Lack of dual-source monthly values prevents overlapping calibration <sup>1</sup>    |

These reconciliation flags do not represent statistical errors but rather serve as a structural record of the unobtained data gaps<sup>1</sup>. By explicitly flagging these checks, the lodging data pipeline is prevented from feeding unverified synthetic data into the Guest Services Scheduling module<sup>1</sup>. This ensures that the energy modeling gates remain secure and that any backcasting steps are triggered through approved fallback pathways rather than utilizing fabricated historical series<sup>1</sup>.

## Pipeline Acquisition Outcomes and Fallback Strategies

Because proprietary constraints and paywalls prevent direct data collection for the 2005–2009 CBRE historical period, the lodging data pipeline must implement a robust fallback strategy to ensure uninterrupted predictive modeling and guest schedule generation<sup>1</sup>.

| Path attempted                                        | Obtained? (Y/N) | If N, why (paywall / no academic access / not found)                                | Recommended fallback the pipeline should record                                                                                             |
|-------------------------------------------------------|-----------------|-------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>CBRE National Market Report archives 2005–2009</b> | N               | Protected by subscription walls and proprietary licensing agreements <sup>1</sup> . | Truncate the SARIMA training window to <b>2010-01</b> (the start of the ABDASH series) or deploy the Statistics Canada Travel Accommodation |

|  |  |  | Services Price Index (TASPI, Table 18-10-0249-01) as an exogenous pricing backcast regressor <sup>1</sup> . |
|--|--|--|-------------------------------------------------------------------------------------------------------------|

Implementing the TASPI price index fallback is supported by hospitality economics, where room rate fluctuations serve as an indirect indicator of physical occupancy pressures<sup>1</sup>. Since hoteliers dynamically adjust rates in response to volume fluctuations, the price index trends can help backcast historical occupancy cycles<sup>1</sup>. This approach allows the downstream SARIMA model to estimate historical demand variations while maintaining the integrity of the distinct data channels<sup>1</sup>.

# Macroeconomic Dynamics and Sectoral Performance

## Synthesis

Analyzing the current lodging market performance and broader macroeconomic indicators reveals a complex relationship between nominal rate growth, physical operational limits, and real purchasing power across the commercial hospitality sector<sup>2</sup>. While direct monthly micro-data for the target 2005–2022 series remains a gap due to reporting and collection constraints, the current verified snapshots from 2025 and 2026 provide crucial insights into the post-pandemic recovery and operational parameters of Alberta's lodging market<sup>2</sup>.

A major structural pattern in the data is the significant performance gap between destination resorts and standard commercial hotels in Alberta<sup>2</sup>. The ABDASH non-resort provincial average is systematically depressed because it excludes premium tourism municipalities such as Banff, Jasper, Canmore, Lake Louise, and Kananaskis<sup>2</sup>. In April 2026, Alberta resorts recorded an average daily room rate (ADR) of \$379.36 and a revenue per available room (RevPAR) of \$209.04<sup>4</sup>. In contrast, the standard provincial average (excluding resorts) was \$155.67 in ADR and \$90.46 in RevPAR<sup>4</sup>.

This represents an ADR premium of 143.7% for resort properties over standard commercial hotels<sup>5</sup>. This premium is driven by high-income domestic and international leisure travelers visiting national parks, which generates highly localized and intensive energy demand cycles<sup>5</sup>. Consequently, utilizing raw, unadjusted provincial averages that include resort properties to model standard urban hotels would artificially inflate occupancy and room rate baselines<sup>1</sup>. This would lead to overestimating internal occupant heat gains in building energy simulations<sup>1</sup>. Therefore, keeping these two data channels separate and applying a spatial calibration factor during the downstream splicing phase is essential for model accuracy<sup>1</sup>.

#### Average Daily Room Rates (ADR) in Alberta (April 2026 Snapshot)

At the regional level, lodging occupancy is also highly sensitive to localized, event-driven demand<sup>11</sup>. This sensitivity is demonstrated by hotel performance in Edmonton and Area during May 2026, where overall occupancy fell by 16% year-over-year<sup>11</sup>. This significant drop is linked to the absence of Edmonton Oilers playoff games compared to the previous year<sup>11</sup>.

This event-dependency highlights that localized occupancy rates are not driven solely by macro-seasonal trends, but can fluctuate based on specific event calendars<sup>11</sup>. For predictive SARIMA models in the GSS→BEM pipeline, these event-driven disruptions must be addressed by integrating exogenous dummy variables to isolate transient spikes and prevent them from distorting the baseline seasonal occupancy curves<sup>1</sup>.

Beyond regional demand drivers, the hospitality sector is facing significant labor supply challenges<sup>7</sup>. In the first quarter of 2026, the accommodation and food services sector registered a job vacancy rate of 5.6%, the highest across all surveyed provincial industries<sup>8</sup>. Additionally, while total provincial tourism employment grew by 9.8% year-over-year to 287,500 in May 2026<sup>7</sup>, a closer look at the accommodation sub-sector reveals structural constraints<sup>7</sup>. Specifically, accommodation sector employment in May 2026 stood at 18,700, representing an 8.1% year-over-year increase from May 2025<sup>7</sup>. However, the year-to-date average for January to May 2026 was down 13.5% at 17,380 compared to 20,100 in the same period of 2025<sup>7</sup>. This year-to-date contraction in the operational workforce, combined with high job vacancy rates, suggests that hotels are facing persistent staffing shortages<sup>7</sup>.

#### Accommodation Sector Employment Trends (YTD Average Jan-May)

This persistent labor shortage functions as a capacity bottleneck<sup>7</sup>. Unable to fully staff housekeeping, guest services, and food operations, some hotels may be forced to limit active room inventory<sup>7</sup>. This operational constraint caps physical occupancy rates, explaining why provincial non-resort occupancy grew by a marginal 0.6 percentage points (58.1% in April 2026 vs 57.5% in April 2025) while nominal room rates expanded by 4.3%<sup>2</sup>. Rather than indicating a lack of market demand, these trends suggest that lodging operations are shifting from volume-driven growth to price-driven yield maximization<sup>2</sup>. This shift allows properties to offset rising labor recruitment costs and maintain profitability<sup>5</sup>. A notable macroeconomic contradiction emerges when comparing nominal hotel rates against broader inflation trends<sup>5</sup>. While nominal non-resort ADR grew by 4.3% in April 2026 (\$155.67 vs \$149.21)<sup>5</sup>, the Alberta Consumer Price Index (CPI) for the "Traveller accommodation" sub-category actually contracted by 1.5% year-over-year in May 2026, following a 2.9% year-to-date decline<sup>9</sup>. This divergence indicates real, inflation-adjusted price compression across the broader commercial lodging sector<sup>5</sup>. While premium properties and resort destinations maintain strong pricing power, midscale and economy hotels are facing real rate compression due to tightening corporate and domestic travel budgets<sup>5</sup>.

For building energy modeling, these labor and pricing dynamics have significant implications<sup>1</sup>. The capacity constraints caused by labor shortages alter the physical occupancy profiles of hotel properties<sup>7</sup>. Reduced on-site staffing levels and lower physical occupancy compress the

internal heat loads generated by guests and staff<sup>1</sup>.

In building energy simulations, this shift directly translates to lower internal heat gains, which reduces estimated cooling loads and increases heating demands during the sub-zero shoulder months in Alberta<sup>1</sup>. BEM workflows must therefore integrate both direct occupancy indicators and external macroeconomic proxies—such as sub-sector employment and CPI lodging indices—to accurately calibrate internal heat gain schedules and improve building performance projections<sup>1</sup>.

## Technical Confidence and Caveats

The lodging performance metrics compiled in this report reflect high structural consistency but absolute historical sparseness<sup>1</sup>. This result aligns with the strict data-hardening guidelines established to eliminate fabricated baselines<sup>1</sup>. While the Alberta Economic Dashboard is confirmed as active and structurally sound, the monthly-level historical time-series tables for the 2010–2022 period were not available in the session's compiled payloads<sup>2</sup>. This limitation necessitated designating those months as gaps<sup>1</sup>.

To populate the historical monthly series for production-grade BEM schedules, users must bypass automated payload queries and perform a direct, manual self-serve export in CSV, XLSX, or JSON format from the official dashboard indicator pages<sup>2</sup>.

For commercial lodging and building energy simulations, relying on unverified or fabricated occupancy rates introduces significant validation risks<sup>1</sup>. If a SARIMA model or guest-room schedule is trained on falsified occupancy inputs, the baseline energy use intensity (EUI) of the simulated building will diverge from actual historical consumption patterns<sup>1</sup>.

Maintaining an audited dataset with marked gaps ensures that the pipeline's truncation and TASPI backcasting systems can deploy their fallback algorithms correctly<sup>1</sup>. Future data collection should focus on securing direct XLSX or CSV exports from the dashboard portal and establishing institutional academic subscriber pathways to the CBRE lodging archives<sup>2</sup>.
